

# README

## Project Overview

This project involves executing a Python script (`Final.py`) that is related to mental health analysis using attention-based autoencoders and Spider Monkey Optimization (SMO) for hyperparameter tuning.

## Prerequisites

Ensure you have the following installed:

- Python 3.x
- Required Python libraries (install via `requirements.txt`)

## Installation

1. Clone the repository or copy the `Final.py` file to your working directory.
2. Install dependencies by running:
3. `pip install -r requirements.txt`

If `requirements.txt` is not available, install necessary libraries manually:

```
pip install numpy pandas scikit-learn tensorflow keras matplotlib seaborn
```

## Execution

Run the script using:

```
python Final.ipynb
```

If additional parameters are required for execution, modify the script accordingly or pass them as command-line arguments.

## Output

- The script will generate and display results, including visualizations if applicable.
- Any output files (e.g., model weights, reports) will be saved in the current directory.

## Troubleshooting

- Ensure all dependencies are installed.
- If using a virtual environment, activate it before running the script:

```
source venv/bin/activate # macOS/Linux
venv\Scripts\activate    # Windows
```
- Check for missing files or incorrect paths in the script.

## Contribution

If you wish to contribute, submit a pull request or raise an issue for discussion.
